

Adrenal gland
Outer layer manufactures steroid hormones that regulate metabolism and maintain fluid balance; inner layer produces adrenaline

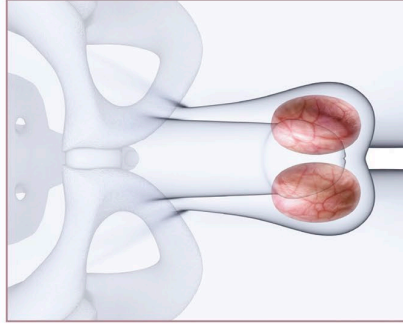

Kidney
Secretes erythropoietin, which stimulates production of red blood cells in bone marrow

Stomach
Makes hormones that stimulate production or release of digestive enzymes

Pancreas
Contains clusters of cells that produce the hormones insulin and glucagon, which control blood glucose levels

Intestines
Like the stomach, make hormones that stimulate production or release of digestive enzymes

Ovary
Makes the female sex hormones oestrogen and progesterone, which regulate the menstrual cycle

TESTES

In males, the two testes produce androgens: male sex hormones, including testosterone. Androgens stimulate the growth and development of the male sexual organs and the production of sperm, and influence secondary sexual characteristics, such as facial hair and deepening of the voice.
