

Trachea

Also called the windpipe, main airway to lungs; held open against pressure of surrounding organs by C-shaped rings of cartilage

Rib

Twelve pairs of ribs curve around chest to protect lungs and heart

Intercostal muscles

Double layer of muscles between each pair of ribs; used during breathing

Right lung

Slightly larger than left lung, averaging 55–60 per cent of total lung volume

Pleural cavity

Space occupied by lungs; lined with lubricated double membranes

Pleural membrane

Comprises two membrane layers enclosing each lung; lubricating fluid reduces friction during breathing

Diaphragm

Dome-shaped muscle dividing chest and abdomen; together with intercostal muscles, forms body's main breathing muscle; during contraction, it flattens to increase size of chest cavity

Pulmonary vein (red)

Vessel that carries oxygenated blood from lung to heart

Pulmonary artery (blue)

Vessel that transports deoxygenated blood to lung from heart

Primary bronchus

Situated outside each lung, main airway supplying lung

Secondary bronchus

Division of one of the two primary bronchi

Tertiary bronchus

Formed from the division of secondary bronchus

Lobes of left lung

Two lobes only, to make room for heart (right lung is three-lobed)

Bronchioles

Terminals of bronchi; gas exchange occurs in minuscule sacs (alveoli) at their ends

Heart

Nested in pericardial cavity

Pericardial cavity

Space formed mainly by a scoop-like shape in left lung
