

PROTISTS (PROTOZOA)

Protists are single-celled organisms with genetic material contained in a nucleus. Animal-like protists, sometimes called protozoa, are common and usually harmless, although some, such as *Plasmodium*, cause serious diseases.

MALARIAL LIFE CYCLE

Five types of *Plasmodium* cause malaria. They are spread by the female *Anopheles* mosquito. Malaria produces chills and high fever, which can recur and prove fatal if not treated. Most *Plasmodium* have a similar life cycle (see below).

TRYPANOSOMES IN BLOOD

Trypanosomes are worm-like protists (purple), seen here with red blood cells. They cause a disease called trypanosomiasis, or sleeping sickness.
