

STRUCTURE OF A NEPHRON

Each nephron consists of two tubes: one for carrying blood and one for forming urine. Both have convoluted routes between the renal cortex and medulla. The blood vessel starts as the afferent arteriole and finishes as a venule that carries the blood away. The

renal tube starts at Bowman's capsule around the glomerulus, and leads into the proximal convoluted tubule, which dips into and out of the medulla as the loop of Henle. Eventually, it feeds urine into a large urine-collecting duct.
