

know what to look for. A change in the color of urine or the presence of blood might also alert you to a problem.

What's normal

- Once your baby has passed the first [dark meconium](#), stools may become dark green, green-yellow, bright yellow, orange, or brown; all are normal and may vary in the same day.
- A baby who is breastfed may have stools that are loose and seedy.
- If your baby is bottle-fed, stools tend to be smooth and firmer.
- Frequency of stools varies from after every feeding to every 2–3 days.
- Urine may be yellow or clear.
- A pink or red-orange stain on the diaper may be due to urate crystals (which form from concentrated urine); these are common in the first few weeks, especially in breastfed babies and are nothing to worry about.

What's not normal

If you notice any of the following changes, you should contact your pediatrician:

- White or putty-colored stools, which could indicate a liver problem.
- Blood mixed in the stools, which could suggest a milk allergy.
- Dark urine, which could be a sign of dehydration or jaundice.
