

Adipose cells

contain a large droplet of fat—one of the body's sources of energy. These cells also help insulate the body.

Dendrites

pick up signals from other neurons

Nerve cells, or neurons, carry electrical signals and make up the brain, the nerves, and the rest of the nervous system—the body's control network.

Muscle cells shorten, or contract, and pull to create movement. In addition to moving the body, they also push food along the intestines and make the heart beat.

Axon, or nerve fiber, carries signals

Photoreceptor cells are sensitive to light and are found inside the eye. When light hits these cells, they send signals to the brain that allow us to see.
