

Seeing

Our most important sense, sight, depends on our two eyes detecting light from our surroundings. Like a digital camera, each eye automatically adjusts its focus to give us clear, sharp images.

The **retina** contains light detectors called rods (white) and cones (green). Cones detect color and detail and work best in strong light, while rods work best in dim light.

Optic nerve carries signals to the brain

Inside the eye

Light enters the eye through the cornea and then passes through the pupil and the lens. The cornea and lens focus the light to form a sharp image on the retina at the back of the eyeball. When hit by light, the retina sends signals along the optic nerve to the brain.

Muscle that moves the eyeball
