

What's in urine?

About 94 percent of urine is water. The rest is dissolved substances that the body does not need. These include urea, the waste product made in the liver, and excess salt.

Water in, water out

Around half of the body's weight is water. As this chart shows, water lost from the body has to be replaced by water taken in for the body to maintain a steady water balance. This includes water that is produced by chemical reactions in cells, known as metabolic water.
