

Lungs and breathing

The human body cannot survive without a nonstop supply of oxygen from the air. The trillions of body cells need constant deliveries of oxygen to release the energy that powers their activities. This process also generates the waste gas carbon dioxide. To get oxygen into the body and to remove carbon dioxide, air is breathed into and out of the lungs.

MISTY BREATH

The air we breathe out, or exhale, contains droplets of water from the lungs. On cold days, these water droplets show up as a fine mist in the air.
