

English ivy

Root clusters on the stem allow this vine to climb to a height of 98 ft (30 m).

Gripping roots

Large, colorful flowers make this climber popular with gardeners.

Clematis

Sticky suckers

Sticky-tipped tendrils grip the wall.

TWINGING STEMS

Plants cannot see so use their tendrils to find something to cling to. Some detect the shade of a nearby object, while others detect chemical signals given off by other plants.

1. Tendril extends outward.

2. It revolves until an object is detected.

3. Tendril wraps around the support.

Virginia creeper, and **flame vine** produce fine tendrils that seek out something to cling to. The stems of **English ivy** sprout clusters of fingerlike aerial roots that burrow into the crevices of the bark, wall, or fence the plant is climbing up. These powerful roots grip so hard, they are difficult to remove and can damage houses and smother trees.

Virginia creeper

The palm-shaped leaves turn bright red in fall.

Flame vine

Two leaflets often share a forked tendril for climbing.

Forked, grasping tendrils
