Himalayas

FACT FILE

- » **Name:** The Himalayas
- » **Height:** 8,848 m (29,029 ft)
- » **Location:** Nepal

Fold mountains

These are the most common type of mountain. They form when two or more tectonic plates are pushed together, causing layers of rock on the seafloor to crumple and fold. Over millions of years, these folded layers are slowly pushed up higher to form mountains.

Volcanic mountains

A volcanic eruption occurs when magma bubbles up and eventually erupts through a crack in the Earth's crust. This causes molten rock, known as lava, to flow over the land, before it cools and hardens. Further eruptions create more layers of hardened lava, which build up to form a mountain.
